Error analysis for full discretizations of quasilinear parabolic problems on evolving surfaces

Balázs Kovács* and Christian Andreas Power Guerra†

April 1, 2015

Abstract

Convergence results are shown for full discretizations of quasilinear parabolic partial differential equations on evolving surfaces. As a semidiscretization in space the evolving surface finite element method is considered, using a regularity result of a generalized Ritz map, optimal order error estimates for the spatial discretization is shown. Combining this with the stability results for Runge–Kutta and BDF time integrators, we obtain convergence results for the fully discrete problems.

Keywords: quasilinear problems, evolving surfaces, ESFEM, Ritz map, Runge–Kutta and BDF methods, energy estimates;

1 Introduction

In this paper we show convergence of full discretizations of quasilinear parabolic partial differential equations on evolving surfaces. As a spatial discretization we consider the evolving surface finite element method. The resulting system of ordinary differential equations is discretized, either with an algebraically stable Runge–Kutta method, or with an implicit or linearly implicit backward differentiation formulae.

To our knowledge [ER15] is the only work on error analysis for nonlinear problems on evolving surfaces. They give semidiscrete error bounds for the Cahn–Hilliard equation. The authors are not aware of fully discrete error estimates published in the literature.

We show convergence results for full discretizations of quasilinear parabolic problems on evolving surfaces with prescribed velocity. We prove unconditional stability and higher-order convergence results for Runge–Kutta and BDF methods. We show convergence as a full discretization when coupled with the ESFEM method as a space discretization for quasilinear problems. Similarly to the linear case the stability analysis is relying on energy estimates and multiplier techniques.

First, we generalize some geometric preturbation estimates to the quasilinear setting. We define a *generalized Ritz map* for quasilinear operators, and use it to show optimal order error estimates for the spatial discretization. During the optimal order L^2-error bounds of the Ritz map we will use a similar argument as Wheeler in [Whe73], and elliptic regularity for evolving surfaces. A further important point of the analysis is the required *regularity* of the generalized Ritz map. This will be used together with the assumed Lipschitz-type estimate for the nonlinearity, analogously as in [DD70, LO95, AL15].

We show stability and convergence results for the case of stiffly accurate algebraically stable implicit Runge–Kutta methods (having the Radau IIA methods in mind), and for an implicit and linearly implicit k-step backward differentiation formulae up to order five. These results are relying on the techniques used in [LO95, DLM12] and [AL15, LMV13]. By combining the results for the spatial semidiscretization with stability and convergence estimates we show high-order convergence bounds for the fully discrete approximation.

A starting point of the finite element approximation to (elliptic) surface partial differential equations is the paper of Dziuk [Dzi88]. Various convergence results for space discretizations of linear parabolic

problems using the evolving surface finite element method (ESFEM) were shown in [DE07a, DE13b], a fully discrete scheme was analysed in [DE12]. These results are surveyed in [DE13a].

The convergence analysis of full discretizations with higher-order time integrators within the ESFEM setting for linear problems were shown: for algebraically stable Runge–Kutta methods in [DLM12]; for backward differentiation formulae (BDF) in [LMV13]. The ESFEM approach and convergence results were later extended to wave equations on evolving surfaces, see [LM15].

A unified presentation of ESFEM and time discretizations for parabolic problems and wave equations can be found in [Man13].

A great number of real-life phenomena are modeled by nonlinear parabolic problems on evolving surfaces. Apart from general quasilinear problems on moving surfaces, see e.g. Example 3.5 in [DE07b], more specific applications are the nonlinear models: diffusion induced grain boundary motion [CFP97, FCE01, Han89, DES01, ES12]; Allen–Cahn and Cahn–Hilliard equations on evolving surfaces [CENC96, EG96, ER15, ES10, Che02]; modeling solid tumor growth [CGG01, ES12]; pattern formation modeled by reaction-diffusion equations [LB02, MB14]; image processing [JYS04]; Ginzburg–Landau model for superconductivity [DJ04].

A number of nonlinear problems, in a general setting, were collected by Dziuk and Elliott in [DE07a, DE07b, DE13a], also see the references therein. A great number of nonlinear problems with numerical experiments were presented in the literature, see e.g. the above references, in particular [DE07a, DE07b, ES12, DES01].

The paper is organized in the following way: In Section 2 we formulate our problem and detail our assumptions. In Section 3 we recall the evolving surface finite element method, together with some of its important properties and estimates. We introduce the generalized Ritz map, and show optimal order error estimates for the residual, using the crucial $W^{1,\infty}$ regularity estimate mentioned above. Section 4 covers the stability results and error estimates for Runge–Kutta and for implicit and linearly implicit BDF methods. Section 5 is devoted to the error bounds of the semidiscrete residual, which then leads to error estimates for the fully discretized problem. In Section 6 we briefly discuss how our results can be extended to semilinear problems, and to the case where the upper and lower bounds of the elliptic part are depending on the norm of the solution. Numerical results are presented in Section 7 to illustrate our theoretical results.

2 The problem and assumptions

Let us consider a sufficiently smooth evolving closed hypersurface $\Gamma(t) \subset \mathbb{R}^{m+1}$ ($m \leq 2$), $0 \leq t \leq T$, which moves with a given smooth velocity v. Let $\partial^\bullet u = \partial_t u + v \cdot \nabla u$ denote the material derivative of the function u, where ∇_Γ is the tangential gradient given by $\nabla_\Gamma u = \nabla u - \nabla u \cdot \nu\nu$, with unit normal ν. We are sharing the setting of [DE07a, DE13b].

We consider the following quasilinear problem for $u = u(x,t)$:

$$\begin{cases} \partial^\bullet u + u\nabla_{\Gamma(t)} \cdot v - \nabla_{\Gamma(t)} \cdot \Big(\mathcal{A}(u)\nabla_{\Gamma(t)} u\Big) = f & \text{on } \Gamma(t), \\ \qquad\qquad\qquad\qquad\qquad\qquad u(.,0) = u_0 & \text{on } \Gamma(0), \end{cases} \tag{1}$$

where $\mathcal{A} : \mathbb{R} \to \mathbb{R}$ is sufficiently smooth function.

Remark 2.1. *The results of the paper can be generalized to the case of a sufficiently smooth matrix valued diffusion coefficient $\mathcal{A}(x,t,u) : T_x\Gamma(t) \to T_x\Gamma(t)$. The proofs are similar to the ones presented here, except they are more technical and lengthy, therefore they are not presented here.*

The abstract setting of this quasilinear evolving surface PDE is a suitable combination of [LO95, Section 1] and [AES14, Section 2.3]: Let $H(t)$ and $V(t)$ be real and separable Hilbert spaces (with norms $\|.\|_{H(t)}$, $\|.\|_{V(t)}$, respectively) such that $V(t)$ is densely and continuously embedded into $H(t)$, and the norm of the dual space of $V(t)$ is denoted by $\|.\|_{V(t)'}$. The dual space of $H(t)$ is identified with itself, and the duality $\langle ., . \rangle_t$ between $V(t)'$ and $V(t)$ coincides on $H(t) \times V(t)$ with the scalar product of $H(t)$, for all $t \in [0,T]$.

The problem casts the following nonlinear operator:

$$\langle A(u)v, w\rangle_t = \int_{\Gamma(t)} \mathcal{A}(u)\nabla_\Gamma v \cdot \nabla_\Gamma w.$$

We assume that A satisfies the following three conditions:
The bilinear form associated to the operator $A(u): V(t) \to V(t)'$ is *elliptic* with $\boldsymbol{m} > 0$

$$\langle A(u)w, w\rangle_t \geq \boldsymbol{m}\|w\|_{V(t)}^2 \qquad (w \in V(t)), \tag{2}$$

uniformly in $u \in V(t)$ and for all $t \in [0,T]$. It is *bounded* with $\mathcal{M} > 0$

$$\big|\langle A(u)v, w\rangle_t\big| \leq \mathcal{M}\|v\|_{V(t)}\|w\|_{V(t)} \qquad (v, w \in V(t)), \tag{3}$$

uniformly in $u \in V(t)$ and for all $t \in [0,T]$. We further assume that there is a subset $\mathcal{S}(t) \subset V(t)$ such that the following *Lipschitz–type* estimate holds: for every $\delta > 0$ there exists $L = L(\delta, (\mathcal{S}(t))_{0\leq t\leq T})$ such that

$$\big\|\big(A(w_1) - A(w_2)\big)u\big\|_{V(t)'} \leq \delta\|w_1 - w_2\|_{V(t)} + L\|w_1 - w_2\|_{H(t)}, \tag{4}$$

for $u \in \mathcal{S}(t),\ w_1, w_2 \in V(t),\ 0 \leq t \leq T$.

The above conditions were also used to prove error estimates using energy techniques in [LO95, DD70], or more recently in [AL15].

The weak formulation uses Sobolev spaces on surfaces: For a sufficiently smooth surface Γ we define

$$H^1(\Gamma) = \big\{\eta \in L^2(\Gamma) \mid \nabla_\Gamma \eta \in L^2(\Gamma)^{m+1}\big\},$$

and analogously $H^k(\Gamma)$ for $k \in \mathbb{N}$ and $W^{k,p}(\Gamma)$ for $k \in \mathbb{N}, p \in [1,\infty]$, cf. [DE07a, Section 2.1]. Finally, $\mathcal{G}_T = \cup_{t\in[0,T]}\Gamma(t) \times \{t\}$ denotes the space-time manifold.

The weak problem corresponding to (1) can be formulated by choosing the setting: $V(t) = H^1(\Gamma(t))$ and $H(t) = L^2(\Gamma(t))$, and the operator:

$$\langle A(u)v, w\rangle_t = \int_{\Gamma(t)} \mathcal{A}(u)\nabla_\Gamma v \cdot \nabla_\Gamma w.$$

The coefficient function $\mathcal{A}: \mathbb{R} \to \mathbb{R}$ satisfies the following conditions.

Assumption 2.1. *(a) It is bounded, and Lipschitz–bounded with constant ℓ.*

(b) The function $\mathcal{A}(s) \geq \boldsymbol{m} > 0$ for arbitrary $s \in \mathbb{R}$.

Throughout the paper we use the following subspace of $V(t)$:

$$\mathcal{S}(t) := \mathcal{S}(t,r) = \big\{u \in H^2(\Gamma(t)) \mid \|u\|_{W^{2,\infty}(\Gamma(t))} \leq r\big\}.$$

Then the following proposition easily follows.

Proposition 2.1. *Under Assumption 2.1 and $u \in \mathcal{S}(t)$ $(0 \leq t \leq T)$ the above operator A satisfies the conditions* (2), (3) *and* (4) *(with $\delta = 0$).*

Proof. The first two conditions (2) and (3) are following from (a) and (b). Condition (4) holds, since for $u \in \mathcal{S}(t)$, $w_1, w_2 \in H^1(\Gamma(t))$ and any $z \in H^1(\Gamma(t))$, we have

$$\begin{aligned}\big|\big\langle (A(w_1) - A(w_2))u, z\big\rangle_t\big| &= \left|\int_{\Gamma(t)} \Big(\mathcal{A}(w_1) - \mathcal{A}(w_2)\Big)\nabla_\Gamma u \cdot \nabla_\Gamma z\right| \\ &\leq c\ell\ \|w_1 - w_2\|_{L^2(\Gamma(t))}\ r\ \|z\|_{H^1(\Gamma(t))},\end{aligned}$$

where the constant ℓ is from Assumption 2.1 (a). ☐

Definition 2.1 (Weak form)**.** *A function $u \in H^1(\mathcal{G}_T)$ is called a* weak solution *of* (1)*, if for almost every $t \in [0,T]$*

$$\frac{\mathrm{d}}{\mathrm{d}t}\int_{\Gamma(t)} u\varphi + \int_{\Gamma(t)} \mathcal{A}(u)\nabla_\Gamma u \cdot \nabla_\Gamma \varphi = \int_{\Gamma(t)} u\partial^\bullet \varphi \tag{5}$$

holds for every $\varphi \in H^1(\mathcal{G}_T)$ and $u(.,0) = u_0$.

3 Spatial semidicretization: evolving surface finite elements

As a spatial semidiscretization we use the evolving surface finite element method introduced by Dziuk and Elliott in [DE07a]. We shortly recall some basic notations and definitions from [DE07a], for more details the reader is referred to Dziuk and Elliott [Dzi88, DE13b, DE13a].

3.1 Basic notations

The smooth surface $\Gamma(t)$ is approximated by a triangulated one denoted by $\Gamma_h(t)$, whose vertives are sitting on the surface, given as

$$\Gamma_h(t) = \bigcup_{E(t)\in\mathcal{T}_h(t)} E(t).$$

We always assume that the (evolving) simplices $E(t)$ are forming an admissible triangulation $\mathcal{T}_h(t)$, with h denoting the maximum diameter. Admissible triangulations were introduced in [DE07a, Section 5.1]: every $E(t)\in\mathcal{T}_h(t)$ satisfies that the inner radius σ_h is bounded from below by ch with $c>0$, and $\Gamma_h(t)$ is not a global double covering of $\Gamma(t)$. Then the discrete tangential gradient on the discrete surface $\Gamma_h(t)$ is given by

$$\nabla_{\Gamma_h(t)}\phi := \nabla\phi - \nabla\phi\cdot\nu_h\nu_h,$$

understood in a piecewise sense, with ν_h denoting the normal to $\Gamma_h(t)$ (see [DE07a]).

For every $t\in[0,T]$ we define the finite element subspace $S_h(t)$ spanned by the continuous, piecewise linear evolving basis functions χ_j, satisfying $\chi_j(a_i(t),t)=\delta_{ij}$ for all $i,j=1,2,\dots,N$, therefore

$$S_h(t) = \operatorname{span}\big\{\chi_1(\,.\,,t),\chi_2(\,.\,,t),\dots,\chi_N(\,.\,,t)\big\}.$$

We interpolate the surface velocity on the discrete surface using the basis functions and denote it with V_h. Then the discrete material derivative is given by

$$\partial_h^\bullet\phi_h = \partial_t\phi_h + V_h\cdot\nabla\phi_h \qquad (\phi_h\in S_h(t)).$$

The key *transport property* derived in [DE07a, Proposition 5.4], is the following

$$\partial_h^\bullet\chi_k = 0 \qquad \text{for} \quad k=1,2,\dots,N. \tag{6}$$

The spatially discrete quasilinear problem for evolving surfaces is formulated in

Problem 3.1 (Semidiscretization in space). *Find $U_h\in S_h(t)$ such that*

$$\frac{\mathrm{d}}{\mathrm{d}t}\int_{\Gamma_h(t)} U_h\phi_h + \int_{\Gamma_h(t)} \mathcal{A}(U_h)\nabla_{\Gamma_h}U_h\cdot\nabla_{\Gamma_h}\phi_h = \int_{\Gamma_h(t)} U_h\partial_h^\bullet\phi_h, \qquad (\forall\phi_h\in S_h(t)), \tag{7}$$

with the initial condition $U_h(\,.\,,0)=U_h^0\in S_h(0)$ being a sufficient approximation to u_0.

3.2 The ODE system

The ODE form of the above problem can be derived by setting

$$U_h(\,.\,,t) = \sum_{j=1}^N \alpha_j(t)\chi_j(\,.\,,t)$$

into (7), testing with $\phi_h=\chi_j$ and using the transport property (6).

Proposition 3.1 (quasilinear ODE system)**.** *The spatially semidiscrete problem* (7) *is equivalent to the following nonlinear ODE system for the vector $\alpha(t)=(\alpha_j(t))\in\mathbb{R}^N$, collecting the nodal values of $U_h(.,t)$:*

$$\begin{cases} \dfrac{\mathrm{d}}{\mathrm{d}t}\Big(M(t)\alpha(t)\Big) + A(\alpha(t))\alpha(t) = 0 \\ \hfill \alpha(0) = \alpha_0 \end{cases} \tag{8}$$

where the evolving mass matrix $M(t)$ and a nonlinear stiffness matrix $A(\alpha(t))$ are defined as

$$M(t)_{kj} = \int_{\Gamma_h(t)} \chi_j \chi_k, \qquad A(\alpha(t))_{kj} = \int_{\Gamma_h(t)} \mathcal{A}\big(U_h\big) \nabla_{\Gamma_h}\chi_j \cdot \nabla_{\Gamma_h}\chi_k,$$

for $\alpha(t)$ defining $U_h = \sum_{j=1}^N \alpha_j(t)\chi_j(.,t)$.

The proof of this proposition is analogous to the corresponding one in [DLM12].

3.3 Discrete Sobolev norm estimates

Through the paper we will work with the norm and semi-norm introduced in [DLM12]. We denote these discrete Sobolev-type norms as

$$|z(t)|_{M(t)} := \|Z_h\|_{L^2(\Gamma_h(t))}, \qquad |z(t)|_{\mathbf{A}(t)} := \|\nabla_{\Gamma_h} Z_h\|_{L^2(\Gamma_h(t))},$$

for arbitrary $z(t) \in \mathbb{R}^N$, where $Z_h(\,.\,,t) = \sum_{j=1}^N z_j(t)\chi_j(\,.\,,t)$, further by $M(t)$ we mean the above mass matrix and by $\mathbf{A}(t)$ we mean the linear (but time dependent) stiffness matrix:

$$\mathbf{A}(t)_{kj} = \int_{\Gamma_h(t)} \nabla_{\Gamma_h}\chi_j \cdot \nabla_{\Gamma_h}\chi_k.$$

A very important lemma in our analysis is the following:

Lemma 3.1 ([DLM12] Lemma 4.1)**.** *There are constants μ, κ (independent of h) such that*

$$\begin{aligned} z^T\big(M(s) - M(t)\big)y &\leq (e^{\mu(s-t)} - 1)|z|_{M(t)}|y|_{M(t)}, \\ z^T\big(\mathbf{A}(s) - \mathbf{A}(t)\big)y &\leq (e^{\kappa(s-t)} - 1)|z|_{\mathbf{A}(t)}|y|_{\mathbf{A}(t)} \end{aligned}$$

for all $y, z \in \mathbb{R}^N$ and $s, t \in [0,T]$.

3.4 Lifting process and approximation results

In the following we recall the so called *lift operator*, which was introduced in [Dzi88] and further investigated in [DE07a, DE13b]. The lift operator projects a finite element function on the discrete surface onto a function on the smooth surface.

Using the *oriented distance function d* ([DE07a, Section 2.1]), for a continuous function $\eta_h \colon \Gamma_h(t) \to \mathbb{R}$ its lift is define as

$$\eta_h^l(p,t) := \eta_h(x,t), \qquad x \in \Gamma(t),$$

where for every $x \in \Gamma_h(t)$ the value $p = p(x,t) \in \Gamma(t)$ is uniquely defined via $x = p + \nu(p,t)d(x,t)$. By η^{-l} we mean the function whose lift is η.

We now recall some notions using the lifting process from [Dzi88, DE07a] and [Man13]. We have the lifted finite element space

$$S_h^l(t) := \big\{\varphi_h = \phi_h^l \,|\, \phi_h \in S_h(t)\big\}.$$

By δ_h we denote the quotient between the continuous and discrete surface measures, $\mathrm{d}A$ and $\mathrm{d}A_h$, defined as $\delta_h \mathrm{d}A_h = \mathrm{d}A$. Further, we recall that

$$\mathrm{Pr} := \big(\delta_{ij} - \nu_i\nu_j\big)_{i,j=1}^{m+1} \quad \text{and} \quad \mathrm{Pr}_h := \big(\delta_{ij} - \nu_{h,i}\nu_{h,j}\big)_{i,j=1}^{m+1}$$

are the projections onto the tangent spaces of Γ and Γ_h. Further, from [DE13b], we recall the notation

$$Q_h = \frac{1}{\delta_h}(I - d\mathcal{H})\mathrm{Pr}\mathrm{Pr}_h\mathrm{Pr}(I - d\mathcal{H}),$$

where $\mathcal{H}$ ($\mathcal{H}_{ij} = \partial_{x_j}\nu_i$) is the (extended) Weingarten map. For these quantities we recall some results from [DE07a, Lemma 5.1], [DE13b, Lemma 5.4] and [Man13, Lemma 6.1].

Lemma 3.2. *Assume that* $\Gamma_h(t)$ *and* $\Gamma(t)$ *is from the above setting, then we have the estimates:*

$$\|d\|_{L^\infty(\Gamma_h(t))} \leq ch^2, \quad \|\nu_j\|_{L^\infty(\Gamma_h(t))} \leq ch, \quad \|1-\delta_h\|_{L^\infty(\Gamma_h(t))} \leq ch^2,$$
$$\|\partial_h^\bullet d\|_{L^\infty(\Gamma_h(t))} \leq ch, \quad \|\mathrm{Pr} - Q_h\|_{L^\infty(\Gamma_h(t))} \leq ch^2, \quad \|\mathrm{Pr}(\partial_h^\bullet Q_h)\mathrm{Pr}\|_{L^\infty(\Gamma_h(t))} \leq ch^2,$$

with constants depending on $\mathcal{G}_T$*, but not on* t*.*

Lemma 3.3. *For* $1 \leq p \leq \infty$ *there exists constants* $c_1, c_2 > 0$ *independent of* t *and* h *such that the for all* $u_h \in W^{1,p}\big(\Gamma_h(t)\big)$ *it holds that* $u_h^l \in W^{1,p}\big(\Gamma(t)\big)$ *with the estimates*

$$c_1 \|u_h\|_{W^{1,p}(\Gamma_h(t))} \leq \|u_h^l\|_{W^{1,p}(\Gamma(t))} \leq c_2 \|u_h\|_{W^{1,p}(\Gamma_h(t))}.$$

Proof. The proofs follows easily from the relation $\nabla_{\Gamma_h} u_h = \mathrm{Pr}_h (I - d\mathcal{H}) \nabla_\Gamma u_h^l$, cf. [Dzi88, Lemma 3]. ☐

3.5 Bilinear forms and their estimates

Apart from the ξ dependence, we use the time dependent bilinear forms defined in [DE13b]: for arbitrary $z, \varphi, \xi \in H^1(\Gamma)$, $\xi \in \mathcal{S}(t)$, and their discrete analogs for $Z_h, \phi_h, \xi_h \in S_h$:

$$\begin{aligned}
m(z,\varphi) &= \int_{\Gamma(t)} z\varphi, & m_h(Z_h,\phi_h) &= \int_{\Gamma_h(t)} Z_h\phi_h \\
a(\xi;z,\varphi) &= \int_{\Gamma(t)} \mathcal{A}(\xi)\nabla_\Gamma z \cdot \nabla_\Gamma \varphi, & a_h(\xi_h;Z_h,\phi_h) &= \int_{\Gamma_h(t)} \mathcal{A}(\xi_h)\nabla_{\Gamma_h} Z_h \cdot \nabla_{\Gamma_h}\phi_h, \\
g(v;z,\varphi) &= \int_{\Gamma(t)} (\nabla_\Gamma \cdot v) z\varphi, & g_h(V_h;Z_h,\phi_h) &= \int_{\Gamma_h(t)} (\nabla_{\Gamma_h} \cdot V_h) Z_h\phi_h, \\
b(\xi;v;z,\varphi) &= \int_{\Gamma(t)} \mathcal{B}(\xi;v)\nabla_\Gamma z \cdot \nabla_\Gamma \varphi, & b_h(\xi_h;V_h;Z_h,\phi_h) &= \int_{\Gamma_h(t)} \mathcal{B}_h(\xi_h;V_h)\nabla_\Gamma Z_h \cdot \nabla_\Gamma \phi_h,
\end{aligned}$$

where the discrete tangential gradients are understood in a piecewise sense, and with the tensors given as

$$\begin{aligned}
\mathcal{B}(\xi;v)_{ij} &= \partial^\bullet(\mathcal{A}(\xi)) + \nabla_\Gamma \cdot v\mathcal{A}(\xi) - 2\mathcal{A}(\xi)\mathcal{D}(v), \\
\mathcal{B}_h(\xi_h;V_h)_{ij} &= \partial_h^\bullet(\mathcal{A}(\xi_h)) + \nabla_{\Gamma_h} \cdot V_h\mathcal{A}(\xi_h) - 2\mathcal{A}(\xi_h)\mathcal{D}_h(V_h),
\end{aligned}$$

with

$$\begin{aligned}
\mathcal{D}(v)_{ij} &= \frac{1}{2}\big((\nabla_\Gamma)_i v_j + (\nabla_\Gamma)_j v_i\big),, \\
\mathcal{D}_h(V_h)_{ij} &= \frac{1}{2}\big((\nabla_{\Gamma_h})_i (V_h)_j + (\nabla_{\Gamma_h})_j (V_h)_i\big),
\end{aligned}$$

for $i, j = 1, 2, \dots, m+1$. For more details see [DE13b, Lemma 2.1] (and the references in the proof), or [DE13a, Lemma 5.2].

We will also use the transport lemma (note that $\partial_h^\bullet z_h = \partial_t z_h + v_h \nabla_\Gamma z_h$ for a $z_h \in S_h^l(t)$):

Lemma 3.4. *For arbitrary* $\xi_h^l \in S_h^l(t)$ *and* z_h, φ_h, $\partial_h^\bullet z_h$, $\partial_h^\bullet \varphi_h \in S_h^l(t)$ *we have:*

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}t} m(z_h,\varphi_h) &= m(\partial_h^\bullet z_h,\varphi_h) + m(z_h,\partial_h^\bullet\varphi_h) + g(v_h;z_h,\varphi_h), \\
\frac{\mathrm{d}}{\mathrm{d}t} a(\xi_h^l;z_h,\varphi_h) &= a(\xi_h^l;\partial_h^\bullet z_h,\varphi_h) + a(\xi_h^l;z_h,\partial_h^\bullet\varphi_h) + b(\xi_h^l;v_h;z_h,\varphi_h),
\end{aligned}$$

where v_h *velocity of the surface.*

Proof. This lemma can be shown analogously as [DE13b, Lemma 4.2], therefore the proof is omitted. ☐

Versions of this lemma with continuous material derivatives, or discrete bilinear forms are also true. The following estimates will play a crucial role in the proofs.

Lemma 3.5 (Geometric perturbation errors)**.** *For any $\xi \in \mathcal{S}(t)$, and $Z_h, \phi_h \in S_h(t)$ with corresponding lifts $z_h, \varphi_h \in S_h^l(t)$ we have the following bounds*

$$\begin{aligned}
\big|m(z_h, \varphi_h) - m_h(Z_h, \phi_h)\big| &\leq ch^2 \|z_h\|_{L^2(\Gamma(t))} \|\varphi_h\|_{L^2(\Gamma(t))}, \\
\big|a(\xi; z_h, \varphi_h) - a_h(\xi^{-l}; Z_h, \phi_h)\big| &\leq ch^2 \|\nabla_\Gamma z_h\|_{L^2(\Gamma(t))} \|\nabla_\Gamma \varphi_h\|_{L^2(\Gamma(t))}, \\
\big|g(v_h; z_h, \varphi_h) - g_h(V_h; Z_h, \phi_h)\big| &\leq ch^2 \|z_h\|_{L^2(\Gamma(t))} \|\varphi_h\|_{L^2(\Gamma(t))}, \\
\big|b(\xi; v_h; z_h, \varphi_h) - b_h(\xi^{-l}; V_h; Z_h, \phi_h)\big| &\leq ch^2 \|\nabla_\Gamma z_h\|_{L^2(\Gamma(t))} \|\nabla_\Gamma \varphi_h\|_{L^2(\Gamma(t))}.
\end{aligned}$$

Proof. The first estimate was proved in [DE13b, Lemma 5.5], while the third can be found in [LM15, Lemma 7.5].

The proof of the second estimate is similar to the linear case found in [DE13a, Lemma 4.7]. Again using the notation from [DE13a]:

$$Q_h = \frac{1}{\delta_h}(I - d\mathcal{H})\mathrm{Pr}\mathrm{Pr}_h\mathrm{Pr}(I - d\mathcal{H})$$

we obtain

$$\mathcal{A}(\xi^{-l})\nabla_{\Gamma_h} Z_h \cdot \nabla_{\Gamma_h} \phi_h = \delta_h \mathcal{A}(\xi^{-l}) Q_h \nabla_\Gamma z_h(p, .) \cdot \nabla_\Gamma \varphi_h(p, .). \tag{9}$$

Similarly as in [DE13b, Lemma 5.5], the boundedness (Proposition 2.1) and the geometric estimate $\|\mathrm{Pr} - Q_h\|_{L^\infty(\Gamma_h)} \leq ch^2$ provides the estimate

$$\begin{aligned}
&\big|a(\xi; z_h, \varphi_h) - a_h(\xi^{-l}; Z_h, \phi_h)\big| \\
&= \Big| \int_{\Gamma(t)} \mathcal{A}(\xi)\nabla_\Gamma z_h \cdot \nabla_\Gamma \varphi_h \mathrm{d}A - \int_{\Gamma_h(t)} \mathcal{A}(\xi^{-l})\nabla_{\Gamma_h} Z_h \cdot \nabla_{\Gamma_h} \phi_h \mathrm{d}A_h \Big| \\
&= \Big| \int_{\Gamma(t)} \mathcal{A}(\xi)\nabla_\Gamma z_h \cdot \nabla_\Gamma \varphi_h \mathrm{d}A - \int_{\Gamma_h(t)} \delta_h \mathcal{A}(\xi^{-l}) Q_h \nabla_\Gamma z_h(p, .) \cdot \nabla_\Gamma \varphi_h(p, .) \mathrm{d}A_h \Big| \\
&= \Big| \int_{\Gamma(t)} \mathcal{A}(\xi)\big(\mathrm{Pr} - Q_h\big)\nabla_\Gamma z_h \cdot \nabla_\Gamma \varphi_h \mathrm{d}A \Big| \\
&\leq \mathcal{M}ch^2 \|\nabla_\Gamma z_h\|_{L^2(\Gamma(t))} \|\nabla_\Gamma \varphi_h\|_{L^2(\Gamma(t))}.
\end{aligned}$$

To prove the fourth estimate we follow [LM15]: starting with the equality

$$\frac{\mathrm{d}}{\mathrm{d}t} \int_{\Gamma_h(t)} \mathcal{A}^{-l}(\xi^{-l})\nabla_{\Gamma_h} Z_h \cdot \nabla_{\Gamma_h} \phi_h = \frac{\mathrm{d}}{\mathrm{d}t} \int_{\Gamma(t)} \mathcal{A}(\xi) Q_h^l \nabla_\Gamma z_h \cdot \nabla_\Gamma \varphi_h$$

then the transport lemma (Lemma 3.4 above) yields

$$\begin{aligned}
&\int_{\Gamma_h(t)} \mathcal{A}(\xi^{-l})\partial_h^\bullet \nabla_{\Gamma_h} Z_h \cdot \nabla_{\Gamma_h} \phi_h + \int_{\Gamma_h(t)} \mathcal{A}^{-l}(\xi^{-l})\nabla_{\Gamma_h} Z_h \cdot \partial_h^\bullet \nabla_{\Gamma_h} \phi_h \\
&\quad + \int_{\Gamma_h(t)} \mathcal{B}_h(\xi^{-l}; V_h)\nabla_{\Gamma_h} Z_h \cdot \nabla_{\Gamma_h} \phi_h \\
&= \int_{\Gamma(t)} \mathcal{A}(\xi) Q_h^l \partial_h^\bullet \nabla_\Gamma z_h \cdot \nabla_\Gamma \varphi_h + \int_{\Gamma(t)} \mathcal{A}(\xi) Q_h^l \nabla_\Gamma z_h \cdot \partial_h^\bullet \nabla_\Gamma \varphi_h \\
&\quad + \int_{\Gamma(t)} \mathcal{B}(\xi; v_h) Q_h^l \nabla_\Gamma z_h \cdot \nabla_\Gamma \varphi_h + \int_{\Gamma(t)} \partial_h^\bullet(\mathcal{A}(\xi) Q_h^l)\nabla_\Gamma z_h \cdot \nabla_\Gamma \varphi_h.
\end{aligned}$$

Therefore using that the lift of $\partial_h^\bullet Z_h$ is $\partial_h^\bullet z_h$, (9) and Lemma 3.2 provides

$$\begin{aligned}
&|b_h(\xi^{-l}; V_h; Z_h, \phi_h) - b(\xi; v_h; Z_h, \phi_h)| \\
&= \Big| \int_{\Gamma(t)} \partial_h^\bullet(\mathcal{A}(\xi) Q_h^l)\nabla_\Gamma z_h \cdot \nabla_\Gamma \varphi_h \Big| + \Big| \int_{\Gamma(t)} \mathcal{B}(\xi; v_h)\big(Q_h^l - I\big)\nabla_\Gamma z_h \cdot \nabla_\Gamma \varphi_h \Big| \\
&\quad \leq ch^2 \|\nabla_\Gamma z_h\|_{L^2(\Gamma(t))} \|\nabla_\Gamma \varphi_h\|_{L^2(\Gamma(t))},
\end{aligned}$$

where the last estimates follow from Lemma 3.2, similarly as in [LM15, Theorem 7.5]. □

3.6 Interpolation estimates

By $I_h \colon H^1\big(\Gamma(t)\big) \to S_h^l(t)$ we denote the finite element interpolation operator, having the error estimate below.

Lemma 3.6. *For $m \leq 3$, there exists a constant $c > 0$ independent of h and t such that for $u \in H^2\big(\Gamma(t)\big)$:*

$$\|u - I_h u\|_{L^2(\Gamma(t))} + h\|\nabla_\Gamma(u - I_h u)\|_{L^2(\Gamma(t))} \leq ch^2\|u\|_{H^2(\Gamma(t))}.$$

Furthermore, if $u \in W^{2,\infty}(\Gamma(t))$, it also satisfies

$$\|\nabla_\Gamma(u - I_h u)\|_{L^\infty(\Gamma(t))} \leq ch\|u\|_{W^{2,\infty}(\Gamma(t))},$$

where $c > 0$ is also independent of h and t.

Proof. The first inequality was shown in [Dzi88]. The dimension restriction is especially discussed in [DE13a, Lemma 4.3].

The analogue of the second estimate for a reference element were shown in [SF73, Theorem 3.1]. Then using standard estimates of the reference element technique we obtain the stated result, cf. [BS08]. $\square$

3.7 The Ritz map for nonlinear problems on evolving surfaces

Ritz maps for quasilinear PDEs on stationary domains were investigated by Wheeler in [Whe73]. We generalize this idea for the case of quasilinear evolving surface PDEs. We define a generalized Ritz map for quasilinear elliptic operators, for the linear case see [LM15].

By combining the above definitions we set the following.

Definition 3.1 (Ritz map). *For a given $z \in H^1(\Gamma(t))$ and a given function $\xi \colon \Gamma(t) \to \mathbb{R}$ there is a unique $\widetilde{\mathcal{P}}_h z \in S_h(t)$ such that for all $\phi_h \in S_h(t)$, with the corresponding lift $\varphi_h = \phi_h^l$, we have*

$$a_h^*(\xi^{-l}; \widetilde{\mathcal{P}}_h z, \phi_h) = a^*(\xi; z, \varphi_h), \tag{10}$$

where $a^* := a + m$ and $a_h^* := a_h + m_h$, to make the forms a and a_h positive definite. Then $\mathcal{P}_h z \in S_h^l(t)$ is defined as the lift of $\widetilde{\mathcal{P}}_h z$, i.e. $\mathcal{P}_h z = (\widetilde{\mathcal{P}}_h z)^l$.

We remind here that by ξ^{-l} we mean a function (living on the discrete surface) whose lift is ξ.

The Galerkin orthogonality does not hold in this case, just up to a small defect:

Lemma 3.7 (pseudo Galerkin orthogonality). *For any given $\xi \in \mathcal{S}(t)$ there holds, that for every $z \in H^1(\Gamma(t))$ and $\varphi_h \in S_h^l(t)$*

$$|a^*(\xi; z - \mathcal{P}_h z, \varphi_h)| \leq ch^2\|\mathcal{P}_h z\|_{H^1(\Gamma(t))}\|\varphi_h\|_{H^1(\Gamma(t))}, \tag{11}$$

where c is independent of ξ, h and t.

Proof. Using the definition of the Ritz map:

$$\begin{aligned} |a^*(\xi; z - \mathcal{P}_h z, \varphi_h)| &= |a_h^*(\xi^{-l}; \widetilde{\mathcal{P}}_h z, \phi_h) - a^*(\xi; \mathcal{P}_h z, \varphi_h)| \\ &\leq \mathcal{M}ch^2\|\mathcal{P}_h z\|_{H^1(\Gamma(t))}\|\varphi_h\|_{H^1(\Gamma(t))}, \end{aligned}$$

where we used Lemma 3.5. $\square$

Error bounds for the Ritz map and for its material derivatives

In this section we prove error estimates for the Ritz map (10) and also for its material derivatives, the analogous results for the linear case can be found in [DE13b, Section 6], [Man13, Section 7]. The ξ independency of the estimates requires extra care, previous results, e.g. the ones cited above, or [LM15, Section 8], are not applicable.

Theorem 3.1. *The error in the Ritz map satisfies the bound, for arbitrary $\xi \in \mathcal{S}(t)$ and $0 \le t \le T$ and $h \le h_0$ with sufficiently small h_0,*

$$\|z - \mathcal{P}_h z\|_{L^2(\Gamma(t))} + h\|z - \mathcal{P}_h z\|_{H^1(\Gamma(t))} \le ch^2 \|z\|_{H^2(\Gamma(t))}.$$

where the constant c is independent of ξ, h and t (but depends on $\boldsymbol{m}$ and $\mathcal{M}$).

Proof. (a) We first prove the gradient estimate.

Starting by the ellipticity of the form a and the non-negativity of the form m, then using the estimate (11) we have:

$$\begin{aligned}
\boldsymbol{m}\|z - \mathcal{P}_h z\|^2_{H^1(\Gamma(t))} &\le a^*(\xi; z - \mathcal{P}_h z, z - \mathcal{P}_h z) \\
&= a^*(\xi; z - \mathcal{P}_h z, z - I_h z) + a^*(\xi; z - \mathcal{P}_h z, I_h z - \mathcal{P}_h z) \\
&\le \mathcal{M}\|z - \mathcal{P}_h z\|_{H^1(\Gamma(t))}\|z - I_h z\|_{H^1(\Gamma(t))} \\
&\quad + ch^2\|\mathcal{P}_h z\|_{H^1(\Gamma(t))}\|I_h z - \mathcal{P}_h z\|_{H^1(\Gamma(t))} \\
&\le \mathcal{M}ch\|z - \mathcal{P}_h z\|_{H^1(\Gamma(t))}\|z\|_{H^2(\Gamma(t))} \\
&\quad + ch^2\Big(2\|z - \mathcal{P}_h z\|^2_{H^1(\Gamma(t))} + \|z\|^2_{H^1(\Gamma(t))} + ch^2\|z\|^2_{H^2(\Gamma(t))}\Big),
\end{aligned}$$

using the interpolation error, and for the second term we used the estimate

$$\begin{aligned}
&\|\mathcal{P}_h z\|_{H^1(\Gamma(t))}\|I_h z - \mathcal{P}_h z\|_{H^1(\Gamma(t))} \\
&\le \Big(\|\mathcal{P}_h z - z\|_{H^1(\Gamma(t))} + \|z\|_{H^1(\Gamma(t))}\Big)\Big(\|I_h z - z\|_{H^1(\Gamma(t))} + \|z - \mathcal{P}_h z\|_{H^1(\Gamma(t))}\Big) \\
&\le 2\|z - \mathcal{P}_h z\|^2_{H^1(\Gamma(t))} + \|z\|^2_{H^1(\Gamma(t))} + ch^2\|z\|^2_{H^2(\Gamma(t))}.
\end{aligned}$$

Now using Young's and Cauchy–Schwarz inequality, and for sufficiently small (but ξ independent) h we have the gradient estimate

$$\|z - \mathcal{P}_h z\|^2_{H^1(\Gamma(t))} \le \frac{1}{\boldsymbol{m}}\mathcal{M}ch^2\|z\|^2_{H^2(\Gamma(t))}.$$

(b) The L^2-estimate follows from the Aubin-Nitsche trick. Let us consider the problem

$$-\nabla_\Gamma \cdot \big(\mathcal{A}(\xi)\nabla_\Gamma w\big) + w = z - \mathcal{P}_h z \qquad \text{on} \quad \Gamma(t),$$

then by elliptic theory, cf. Theorem A.1, we have the estimate, for the solution $w \in H^2(\Gamma(t))$

$$\|w\|_{H^2(\Gamma(t))} \le c\|z - \mathcal{P}_h z\|_{L^2(\Gamma(t))},$$

where c is independent of t and ξ. By testing the elliptic weak problem with $z - \mathcal{P}_h z$ we have

$$\begin{aligned}
\|z - \mathcal{P}_h z\|^2_{L^2(\Gamma(t))} &= a^*(\xi; z - \mathcal{P}_h z, w) \\
&= a^*(\xi; z - \mathcal{P}_h z, w - I_h w) + a^*(\xi; z - \mathcal{P}_h z, I_h w) \\
&\le \mathcal{M}\|z - \mathcal{P}_h z\|_{H^1(\Gamma(t))}\|w - I_h w\|_{H^1(\Gamma(t))} \\
&\quad + ch^2\|\mathcal{P}_h z\|_{H^1(\Gamma(t))}\|I_h w\|_{H^1(\Gamma(t))}.
\end{aligned}$$

Then the estimates of the interpolation error and combination of the above results yields

$$\|z - \mathcal{P}_h z\|_{L^2(\Gamma(t))}\frac{1}{c}\|w\|_{H^2(\Gamma(t))} \le \|z - \mathcal{P}_h z\|^2_{L^2(\Gamma(t))} \le \mathcal{M}ch^2\|z\|_{H^2(\Gamma(t))}\|w\|_{H^2(\Gamma(t))},$$

which completes the proof of the first assertion. ☐

We will also need the following error estimates for the material derivatives of the Ritz map.

Theorem 3.2. *The error in the material derivatives of the Ritz map satisfies the bounds, for $k \ge 1$, and for arbitrary $\xi \in \mathcal{S}(t)$ and $0 \le t \le T$ and $h \le h_0$ with sufficiently small h_0,*

$$\|(\partial_h^\bullet)^{(k)}(z - \mathcal{P}_h z)\|_{L^2(\Gamma(t))} + h\|\nabla_\Gamma(\partial_h^\bullet)^{(k)}(z - \mathcal{P}_h z)\|_{L^2(\Gamma(t))} \le \mathcal{M}c_k h^2 \sum_{j=1}^{k} \|(\partial_h^\bullet)^{(j)} z\|_{H^2(\Gamma(t))}.$$

The constant $c_k > 0$ is independent of ξ and h (but depends on α and $\mathcal{M}$).

Proof. The proof is a modification of [Man13, Theorem 7.3].

For $k = 1$: (a) We start by taking the time derivative of the definition of the Ritz map (10), use the transport properties (Lemma 3.4), and use the definition of the Ritz map once more, we arrive at

$$\begin{aligned} a^*(\xi; \partial_h^\bullet z, \varphi_h) = &-b(\xi; v_h; z, \varphi_h) - g(v_h; z, \varphi_h) \\ &+a_h^*(\xi^{-l}; \partial_h^\bullet \widetilde{\mathcal{P}}_h z, \phi_h) + b_h(\xi^{-l}; V_h; \widetilde{\mathcal{P}}_h z, \phi_h) + g_h(V_h; \widetilde{\mathcal{P}}_h z, \phi_h). \end{aligned}$$

Then we obtain

$$\begin{aligned} a^*(\xi; \partial_h^\bullet z - \partial_h^\bullet \mathcal{P}_h z, \varphi_h) = &- b(\xi; v_h; z - \mathcal{P}_h z, \varphi_h) - g(v_h; z - \mathcal{P}_h z, \varphi_h) \\ &+ F_1(\varphi_h), \end{aligned} \tag{12}$$

where

$$\begin{aligned} F_1(\varphi_h) = &\big(a_h^*(\xi^{-l}; \partial_h^\bullet \widetilde{\mathcal{P}}_h z, \phi_h) - a^*(\xi; \partial_h^\bullet \mathcal{P}_h z, \varphi_h)\big) \\ &+ \big(b_h(\xi^{-l}; V_h; \widetilde{\mathcal{P}}_h z, \phi_h) - b(\xi; v_h; \mathcal{P}_h z, \varphi_h)\big) \\ &+ \big(g_h(V_h; \widetilde{\mathcal{P}}_h z, \phi_h) - g(v_h; \mathcal{P}_h z, \varphi_h)\big). \end{aligned}$$

Using the geometric estimates of Lemma 3.5 F_1 can be estimated as

$$\big|F_1(\varphi_h)\big| \leq c\mathcal{M}h^2\big(\|\partial_h^\bullet \mathcal{P}_h z\|_{H^1(\Gamma(t))} + \|\mathcal{P}_h z\|_{H^1(\Gamma(t))}\big)\|\varphi_h\|_{H^1(\Gamma(t))}.$$

Then using $\partial_h^\bullet \mathcal{P}_h z$ as a test function in (12), and using the error estimates of the Ritz map, together with the estimates above, with $h \leq h_0$ independent of ξ, we have

$$\|\partial_h^\bullet \mathcal{P}_h z\|_{H^1(\Gamma(t))} \leq \mathcal{M}c\|\partial^\bullet z\|_{H^1(\Gamma(t))} + \mathcal{M}ch\|z\|_{H^2(\Gamma(t))}.$$

Combining all the previous estimates and using Young's inequality, Cauchy–Schwarz inequality, for sufficiently small (ξ independent) $h \leq h_0$, we obtain

$$a^*(\xi; \partial_h^\bullet z - \partial_h^\bullet \mathcal{P}_h z, \varphi_h) \leq \mathcal{M}ch\Big(\|z\|_{H^2(\Gamma(t))} + h\|\partial^\bullet z\|_{H^1(\Gamma(t))}\Big)\|\varphi_h\|_{H^1(\Gamma(t))}.$$

Then as in the previous proof we have

$$\begin{aligned} \boldsymbol{m}\|\partial_h^\bullet z - \partial_h^\bullet \mathcal{P}_h z\|_{H^1(\Gamma(t))}^2 &\leq a^*(\xi; \partial_h^\bullet z - \partial_h^\bullet \mathcal{P}_h z, \partial_h^\bullet z - \partial_h^\bullet \mathcal{P}_h z) \\ &= a^*(\xi; \partial_h^\bullet z - \partial_h^\bullet \mathcal{P}_h z, \partial_h^\bullet z - I_h\partial^\bullet z) + a^*(\xi; \partial_h^\bullet z - \partial_h^\bullet \mathcal{P}_h z, I_h\partial^\bullet z - \partial_h^\bullet \mathcal{P}_h z) \\ &\leq \mathcal{M}\|\partial_h^\bullet z - \partial_h^\bullet \mathcal{P}_h z\|_{H^1(\Gamma(t))}\|\partial_h^\bullet z - I_h\partial^\bullet z\|_{H^1(\Gamma(t))} \\ &\quad + \mathcal{M}ch\Big(\|z\|_{H^2(\Gamma(t))} + h\|\partial^\bullet z\|_{H^1(\Gamma(t))}\Big)\|I_h\partial^\bullet z - \partial_h^\bullet \mathcal{P}_h z\|_{H^1(\Gamma(t))}. \end{aligned}$$

Then the interpolation estimates, Young's inequality, absorption using $h \leq h_0$, yields the gradient estimate.

(b) The L^2-estimate again follows from the Aubin-Nitsche trick. Let us now consider the problem

$$-\nabla_\Gamma \cdot \big(\mathcal{A}(\xi)\nabla_\Gamma w\big) + w = \partial_h^\bullet z - \partial_h^\bullet \mathcal{P}_h z \qquad \text{on} \quad \Gamma(t),$$

together with the elliptic estimate (cf. Theorem A.1), for the solution $w \in H^2(\Gamma(t))$

$$\|w\|_{H^2(\Gamma(t))} \leq c\|\partial_h^\bullet z - \partial_h^\bullet \mathcal{P}_h z\|_{L^2(\Gamma(t))},$$

again, c is independent of t and ξ.

Then a similar calculation as [DE13b, Theorem 6.2], [Man13, Theorem 7.3] provides the L^2-norm estimate.

For $k > 1$ the proof is analogous. □

Regularity of the Ritz map

The following technical result will play an important role in showing optimal bounds of the semidiscrete residual.

Lemma 3.8. *For $m \leq 2$, there exists a constant $c > 0$ independent of h and t such that for a function $u \in W^{2,\infty}(\Gamma(t))$ for all $t \in [0,T]$, the following estimate holds*

$$\|\nabla_\Gamma \mathcal{P}_h u\|_{L^\infty(\Gamma(t))} \leq c\|u\|_{W^{2,\infty}(\Gamma(t))}.$$

Proof. Using the triangle inequality we start to estimate as

$$\begin{aligned}\|\nabla_\Gamma \mathcal{P}_h u\|_{L^\infty(\Gamma(t))} \leq{}& \|\nabla_\Gamma(\mathcal{P}_h u - I_h u)\|_{L^\infty(\Gamma(t))} + \|\nabla_\Gamma(I_h u - u)\|_{L^\infty(\Gamma(t))} \\ &+ \|\nabla_\Gamma u\|_{L^\infty(\Gamma(t))}.\end{aligned}$$

The last term is harmless. The second term is estimated using Lemma 3.6. For the first term, using the inverse estimate, error estimates for the Ritz map and for the interpolation operator we obtain

$$\begin{aligned}\|\nabla_\Gamma(\mathcal{P}_h u - I_h u)\|_{L^\infty(\Gamma(t))} &\leq ch^{-m/2}\|\nabla_\Gamma(\mathcal{P}_h u - I_h u)\|_{L^2(\Gamma(t))} \\ &\leq ch^{-m/2}\Big(\|\nabla_\Gamma(\mathcal{P}_h u - u)\|_{L^2(\Gamma(t))} + \|\nabla_\Gamma(u - I_h u)\|_{L^2(\Gamma(t))}\Big) \\ &\leq ch^{-m/2}h\|u\|_{H^2(\Gamma(t))} \leq c\|u\|_{W^{2,\infty}(\Gamma(t))}.\end{aligned}$$

□

Remark 3.1. *A stronger result holds, assuming that $u \in W^{1,\infty}(\Gamma(t))$, the bound $\|\nabla_\Gamma \mathcal{P}_h u\|_{L^\infty(\Gamma(t))} \leq c\|u\|_{W^{1,\infty}(\Gamma(t))}$ can be shown. However, the proof is technical and requires more sophisticated arguments, cf. [Pow]. This enables to weaken the assumption to $W^{1,\infty}$ in the definition of the $\mathcal{S}(t)$ set. We do not include these results here because of their length.*

4 Time discretizations: stability

4.1 Runge–Kutta methods

We consider an s-stage algebraically stable implicit Runge–Kutta (R–K) method for the time discretization of the ODE system (8), coming from the ESFEM space discretization of the quasilinear parabolic evolving surface PDE.

In the following we extend the stability result for R–K methods of [DLM12, Lemma 7.1], to the case of quasilinear problems. Apart form the properties of the ESFEM the proof is based on the energy estimation techniques, see Lubich and Ostermann [LO95, Theorem 1.1]. Generally on Runge–Kutta methods we refer to [HW96].

For the convenience of the reader we recall the method: for simplicity, we assume equidistant time steps $t_n := n\tau$, with step size τ. Our results can be straightforwardly extended to the case of nonuniform time steps. The s-stage implicit Runge–Kutta method, defined by the given Butcher tableau

$$\begin{array}{c|c} (c_i) & (a_{ij}) \\ \hline & (b_i) \end{array} \qquad \text{for} \quad i,j = 1,2,\dots,s,$$

applied to the system (8), reads as

$$\begin{aligned} M_{ni}\alpha_{ni} &= M_n\alpha_n + \tau\sum_{j=1}^{s} a_{ij}\dot\alpha_{nj}, \qquad \text{for} \quad i = 1,2,\dots,s, \\ M_{n+1}\alpha_{n+1} &= M_n\alpha_n + \tau\sum_{i=1}^{s} b_i\dot\alpha_{ni}, \end{aligned}$$

where the internal stages satisfy

$$0 = \dot\alpha_{ni} + A(\alpha_{ni})\alpha_{ni} \qquad \text{for} \quad i = 1,2,\dots,s,$$

with $M_{ni} := M(t_n + c_i\tau)$ and $M_{n+1} := M(t_{n+1})$. Here $\dot{\alpha}_{ni}$ is not a derivative but a suggestive notation.

We recall that the fully discrete solution is $U_h^n = \sum_{j=1}^N \alpha_{n,j}\chi_j(\,.\,, t_n)$.

For the R–K method we make the following assumptions:

Assumption 4.1.

- *The method has stage order $q \geq 1$ and classical order $p \geq q+1$.*
- *The coefficient matrix (a_{ij}) is invertible.*
- *The method is* algebraically stable*, i.e. $b_j > 0$ for $j = 1, 2, \ldots, s$ and the following matrix is positive semi-definite:*

$$\big(b_i a_{ij} - b_j a_{ji} - b_i b_j\big)_{i,j=1}^s.$$

- *The method is* stiffly accurate*, i.e. $b_j = a_{sj}$, and $c_s = 1$ for $j = 1, 2, \ldots, s$.*

Instead of (8), let us consider the following perturbed version of the equation:

$$\begin{cases} \dfrac{\mathrm{d}}{\mathrm{d}t}\big(M(t)\widetilde{\alpha}(t)\big) + A(\widetilde{\alpha}(t))\widetilde{\alpha}(t) = M(t)r(t) \\ \qquad\qquad\qquad\qquad\qquad \widetilde{\alpha}(0) = \widetilde{\alpha}_0. \end{cases} \tag{14}$$

The substitution of the true solution $\widetilde{\alpha}(t)$ of the perturbed problem into the R–K method, yields the defects Δ_{ni} and δ_{ni}, by setting $e_n = \alpha_n - \widetilde{\alpha}(t_n)$, $E_{ni} = \alpha_{ni} - \widetilde{\alpha}(t_n + c_i\tau)$ and $\dot{E}_{ni} = \dot{\alpha}_{ni} - \dot{\widetilde{\alpha}}(t_n + c_i\tau)$, then by subtraction the following *error equations* hold:

$$\begin{aligned} M_{ni}E_{ni} &= M_n e_n + \tau\sum_{j=1}^s a_{ij}\dot{E}_{nj} - \Delta_{ni}, \qquad \text{for} \quad i = 1, 2, \ldots, s, \\ M_{n+1}e_{n+1} &= M_n e_n + \tau\sum_{i=1}^s b_i\dot{E}_{ni} - \delta_{n+1}, \end{aligned}$$

where the internal stages satisfy:

$$\dot{E}_{ni} + A(\alpha_{ni})E_{ni} = -\big(A(\alpha_{ni}) - A(\widetilde{\alpha}_{ni})\big)\widetilde{\alpha}_{ni} - M_{ni}r_{ni}, \quad \text{for} \quad i = 1, 2, \ldots, s,$$

with $r_{ni} := r(t_n + c_i\tau)$.

Now we state one of the key lemmas of this paper, which provide unconditional stability for the above class of Runge–Kutta methods.

Lemma 4.1. *For an s-stage implicit Runge–Kutta method satisfying Assumption 4.1. If the equation* (5) *has a solution in $\mathcal{S}(t)$ for $0 \leq t \leq T$. Then there exists a $\tau_0 > 0$, such that for $\tau \leq \tau_0$ and $t_n = n\tau \leq T$, that the error e_n is bounded by*

$$\begin{aligned} |e_n|_{M_n}^2 + \tau\sum_{k=1}^n |e_k|_{\mathbf{A}_k}^2 \leq & C\bigg(|e_0|_{M_0} + \tau\sum_{k=1}^{n-1}\sum_{i=1}^s \|M_{ki}r_{ki}\|_{*,t_{ki}}^2 + \tau\sum_{k=1}^n \Big|\frac{\delta_k}{\tau}\Big|_{M_k}^2 \\ & + C\tau\sum_{k=0}^{n-1}\sum_{i=1}^s\Big(|M_{ki}^{-1}\Delta_{ki}|_{M_{ki}}^2 + |M_{ki}^{-1}\Delta_{ki}|_{\mathbf{A}_{ki}}^2\Big)\bigg), \end{aligned}$$

where $\|w\|_{*,t}^2 = w^T(\mathbf{A}(t) + M(t))^{-1}w$. The constant C is independent of h, τ and n (but depends on $\boldsymbol{m}$, $\mathcal{M}$, L, μ, κ and T).

Proof. The combination of proofs of Theorem 1.1 from [LO95] and of Lemma 7.1 from [DLM12] (or [Man13, Lemma 3.1]) suffices, therefore it is omitted here. To be precise, the proof of this result is more closely related to [DLM12], except the estimates involving the internal stages are more similar to [LO95]. ☐

Then, using the above stability results, the error bounds are following analogously as in [DLM12, Theorem 8.1] (or [Man13, Theorem 5.1]).

Theorem 4.1. *Consider the quasilinear parabolic problem* (1)*, having a solution in* $\mathcal{S}(t)$ *for* $0 \le t \le T$*. Couple the evolving surface finite element method as space discretization with time discretization by an s-stage implicit Runge–Kutta method satisfying Assumption 4.1. Assume that the Ritz map of the solution has continuous discrete material derivatives up to order* $q+2$*. Then there exists* $\tau_0 > 0$*, independent of* h*, such that for* $\tau \le \tau_0$*, for the error* $E_h^n = U_h^n - \mathcal{P}_h u(.,t_n)$ *the following estimate holds for* $t_n = n\tau \le T$*:*

$$\|E_h^n\|_{L^2(\Gamma_h(t_n))} + \Big(\tau \sum_{j=1}^n \|\nabla_{\Gamma_h(t_j)} E_h^j\|^2_{L^2(\Gamma_h(t_j))}\Big)^{\frac12}$$

$$\le C\tilde\beta_{h,q}\tau^{q+1} + C\Big(\tau\sum_{k=0}^{n-1}\sum_{i=1}^s \|R_h(.,t_k+c_i\tau)\|^2_{H^{-1}(\Gamma_h(t_k+c_i\tau))}\Big)^{\frac12} + C\|E_h^0\|_{L^2(\Gamma_h(0))},$$

where the constant C *is independent of* h*,* τ *and* n *(but depends on* $\boldsymbol{m}$*,* $\mathcal{M}$*,* L*,* μ*,* κ *and* T*). Furthermore*

$$\tilde\beta_{h,q}^2 = \int_0^T \sum_{\ell=1}^{q+2} \|(\partial_h^\bullet)^{(\ell)}(\mathcal{P}_h u)(.,t)\|_{L^2(\Gamma_h(t))}\mathrm{d}t$$

$$+ \int_0^T \sum_{\ell=1}^{q+1} \|\nabla_{\Gamma_h(t)}(\partial_h^\bullet)^{(\ell)}(\mathcal{P}_h u)(.,t)\|_{L^2(\Gamma_h(t))}\mathrm{d}t.$$

The H^{-1} *norm of* R_h *is defined as*

$$\|R_h(.,t)\|_{H^{-1}(\Gamma_h(t))} := \sup_{0\ne\phi_h\in S_h(t)} \frac{\langle R_h(.,t),\phi_h\rangle_{L^2(\Gamma_h(t))}}{\|\phi_h\|_{H^1(\Gamma_h(t))}} .$$

4.2 Backward differentiation formulae

We apply a k-step backward difference formula (BDF) for $k \le 5$ as a discretization to the ODE system (8), coming from the ESFEM space discretization of the quasilinear parabolic evolving surface PDE. Both implicit and linearly implicit methods are discussed.

In the following we extend the stability result for BDF methods of [LMV13, Lemma 4.1], to the case quasilinear problems. Apart from the properties of the ESFEM the proof is based on Dahlquist's G–stability theory [Dah78] and on the multiplier technique of Nevanlinna and Odeh [NO81].

We recall the k-step BDF method for (8) with step size $\tau > 0$:

$$\frac{1}{\tau}\sum_{j=0}^k \delta_j M(t_{n-j})\alpha_{n-j} + A(\alpha_n)\alpha_n = 0, \qquad (n \ge k), \tag{16}$$

where the coefficients of the method are given by $\delta(\zeta) = \sum_{j=0}^k \delta_j\zeta^j = \sum_{\ell=1}^k \frac{1}{\ell}(1-\zeta)^\ell$, while the starting values are $\alpha_0, \alpha_1, \dots, \alpha_{k-1}$. The method is known to be 0-stable for $k \le 6$ and have order k (for more details, see [HW96, Chapter V.]).

Similarly linearly implicit method modification is, using the polynomial $\gamma(\zeta) = \sum_{j=1}^k \gamma_j\zeta^j = \zeta^k - (\zeta-1)^{k-1}$:

$$\frac{1}{\tau}\sum_{j=0}^k \delta_j M(t_{n-j})\alpha_{n-j} + A\Big(\sum_{j=1}^k \gamma_j\alpha_{n-j}\Big)\alpha_n = 0, \qquad (n \ge k). \tag{17}$$

For more details we refer to [AL15].

Instead of (8) let us consider again the perturbed problem (14). By substituting the true solution $\widetilde\alpha(t)$ of the perturbed problem into the BDF method (16), we obtain

$$\frac{1}{\tau}\sum_{j=0}^k \delta_j M(t_{n-j})\widetilde\alpha_{n-j} + A(\widetilde\alpha_n)\widetilde\alpha_n = -d_n, \qquad (n \ge k).$$

By introducing the error $e_n = \alpha_n - \widetilde\alpha(t_n)$, multiplying by τ, and by subtraction we have the error equation

$$\sum_{j=0}^k \delta_j M_{n-j}e_{n-j} + \tau A(\alpha_n)e_n + \tau\big(A(\alpha_n) - A(\widetilde\alpha_n)\big)\widetilde\alpha_n = \tau d_n, \quad (n \ge k).$$

In the linearly implicit case we obtain:

$$\sum_{j=0}^{k}\delta_j M_{n-j}e_{n-j}+\tau A\Big(\sum_{j=1}^{k}\gamma_j\alpha_{n-j}\Big)e_n+\tau\Big(A\Big(\sum_{j=1}^{k}\gamma_j\alpha_{n-j}\Big)-A\Big(\sum_{j=1}^{k}\gamma_j\widetilde{\alpha}_{n-j}\Big)\Big)\widetilde{\alpha}_n=\tau\hat{d}_n,\quad (n\geq k),$$

where $\hat{d}_n$ have similar properties as d_n, therefore it will be also denoted by d_n.

The stability results for BDF methods are the following.

Lemma 4.2. *For a k-step implicit or linearly implicit BDF method with $k\leq 5$ there exists a $\tau_0>0$, such that for $\tau\leq\tau_0$ and $t_n=n\tau\leq T$, that the error e_n is bounded by*

$$|e_n|_{M_n}^2+\tau\sum_{j=k}^{n}|e_j|_{\mathbf{A}_j}^2\leq C\tau\sum_{j=k}^{n}\|d_j\|_{*,t_j}^2+C\max_{0\leq i\leq k-1}|e_i|_{M_i}^2$$

where $\|w\|_{*,t}^2=w^T(\mathbf{A}(t)+M(t))^{-1}w$. The constant C is independent of h,τ and n (but depends on $\boldsymbol{m}$, $\mathcal{M}$, L, μ, κ and T).

Proof. The proof follows the proof of Lemma 4.1 from [LMV13] (using G-stability from [Dah78] and multiplier techniques from [NO81]), except in those terms where the nonlinearity appears. For their estimates we refer to Theorem 1 in [AL15]. For linearly implicit methods we follow [AL15, Section 6]. Therefore these proofs are also omitted. □

Again, using the above stability results, the error bounds are following analogously as in [LMV13, Theorem 5.1] (or [Man13, Theorem 5.3]).

Theorem 4.2. *Consider the quasilinear parabolic problem* (1)*, having a solution in $\mathcal{S}(t)$ for $0\leq t\leq T$. Couple the evolving surface finite element method as space discretization with time discretization by a k-step implicit or linearly implicit backward difference formula of order $k\leq 5$. Assume that the Ritz map of the solution has continuous discrete material derivatives up to order $k+1$. Then there exists $\tau_0>0$, independent of h, such that for $\tau\leq\tau_0$, for the error $E_h^n=U_h^n-\mathcal{P}_h u(.,t_n)$ the following estimate holds for $t_n=n\tau\leq T$:*

$$\begin{aligned}\|E_h^n\|_{L^2(\Gamma_h(t_n))}&+\Big(\tau\sum_{j=1}^{n}\|\nabla_{\Gamma_h(t_j)}E_h^j\|_{L^2(\Gamma_h(t_j))}^2\Big)^{\frac12}\\&\leq C\tilde{\beta}_{h,k}\tau^k+\Big(\tau\sum_{j=1}^{n}\|R_h(.,t_j)\|_{H^{-1}(\Gamma_h(t_j))}^2\Big)^{\frac12}+C\max_{0\leq i\leq k-1}\|E_h^i\|_{L^2(\Gamma_h(t_i))},\end{aligned}$$

where the constant C is independent of h,n and τ (but depends on $\boldsymbol{m}$, $\mathcal{M}$, L, μ, κ and T). Furthermore

$$\tilde{\beta}_{h,k}^2=\int_0^T\sum_{\ell=1}^{k+1}\|(\partial_h^\bullet)^{(\ell)}(\mathcal{P}_h u)(.,t)\|_{L^2(\Gamma_h(t))}\mathrm{d}t.$$

5 Error bounds for the fully discrete solutions

We follow the approach of [LMV13, Section 5] by defining the FEM residual $R_h(.,t)=\sum_{j=1}^{N}r_j(t)\chi_j(.,t)\in S_h(t)$ as

$$\int_{\Gamma_h}R_h\phi_h=\frac{\mathrm{d}}{\mathrm{d}t}\int_{\Gamma_h}\mathcal{P}_h u\phi_h+\int_{\Gamma_h}\mathcal{A}(\mathcal{P}_h u)\nabla_\Gamma(\mathcal{P}_h u)\cdot\nabla_\Gamma\phi_h-\int_{\Gamma_h}(\mathcal{P}_h u)\partial_h^\bullet\phi_h,\tag{18}$$

where $\phi_h\in S_h(t)$, and the Ritz map of the true solution u is given as

$$\widetilde{\mathcal{P}}_h u(.,t)=\sum_{j=1}^{N}\widetilde{\alpha}_j(t)\chi_j(.,t).$$

The above problem is equivalent to the ODE system with the vector $r(t)=(r_j(t))\in\mathbb{R}^N$:

$$\frac{\mathrm{d}}{\mathrm{d}t}\big(M(t)\widetilde{\alpha}(t)\big)+A(\widetilde{\alpha}(t))\widetilde{\alpha}(t)=M(t)r(t),$$

which is the perturbed ODE system (14).

5.1 Bound of the semidiscrete residual

We now show the optimal second order estimate of the residual R_h.

Theorem 5.1. *Let u, the solution of the parabolic problem, be in $\mathcal{S}(t)$ for $0 \leq t \leq T$. Then there exists a constant $C > 0$ and $h_0 > 0$, such that for all $h \leq h_0$ and $t \in [0, T]$, the finite element residual R_h of the Ritz map is bounded as*

$$\|R_h\|_{H^{-1}(\Gamma_h(t))} \leq Ch^2.$$

Proof. (a) We start by applying the discrete transport property to the residual equation (18)

$$\begin{aligned} m_h(R_h, \phi_h) &= \frac{\mathrm{d}}{\mathrm{d}t} m_h(\widetilde{\mathcal{P}}_h u, \phi_h) + a_h(\widetilde{\mathcal{P}}_h u; \widetilde{\mathcal{P}}_h u, \phi_h) - m_h(\widetilde{\mathcal{P}}_h u, \partial_h^\bullet \phi_h) \\ &= m_h(\partial_h^\bullet \widetilde{\mathcal{P}}_h u, \phi_h) + a_h(\widetilde{\mathcal{P}}_h u; \widetilde{\mathcal{P}}_h u, \phi_h) + g_h(V_h; \widetilde{\mathcal{P}}_h u, \phi_h). \end{aligned}$$

(b) We continue by the transport property with discrete material derivatives from Lemma 3.4, but for the weak form, with $\varphi := \varphi_h = (\phi_h)^l$:

$$\begin{aligned} 0 &= \frac{\mathrm{d}}{\mathrm{d}t} m(u, \varphi_h) + a(u; u, \varphi_h) - m(u, \partial^\bullet \varphi_h) \\ &= m(\partial_h^\bullet u, \varphi_h) + a(u; u, \varphi_h) + g(v_h; u, \varphi_h) + m(u, \partial_h^\bullet \varphi_h - \partial^\bullet \varphi_h). \end{aligned}$$

(c) Subtraction of the two equations, using the definition of the Ritz map with $\xi = u$ in (10), i.e.

$$a_h^*(u^{-l}; \widetilde{\mathcal{P}}_h u, \phi_h) = a^*(u; u, \varphi_h),$$

and using that

$$\partial_h^\bullet \varphi_h - \partial^\bullet \varphi_h = (v_h - v) \cdot \nabla_\Gamma \varphi_h$$

holds, we obtain

$$\begin{aligned} m_h(R_h, \phi_h) = {} & m_h(\partial_h^\bullet \widetilde{\mathcal{P}}_h u, \phi_h) - m(\partial_h^\bullet u, \varphi_h) \\ & + g_h(V_h; \widetilde{\mathcal{P}}_h u, \phi_h) - g(v_h; u, \varphi_h) \\ & + a_h^*(\widetilde{\mathcal{P}}_h u; \widetilde{\mathcal{P}}_h u, \phi_h) - a_h^*(u^{-l}; \widetilde{\mathcal{P}}_h u, \phi_h) \\ & + m(u, \varphi_h) - m_h(\widetilde{\mathcal{P}}_h u, \phi_h) \\ & + m(u, (v_h - v) \cdot \nabla_\Gamma \varphi_h). \end{aligned}$$

All the pairs can be easily estimated separately as $ch^2 \|\varphi_h\|_{L^2(\Gamma(t))}$, by combining the estimates of Lemma 3.5, and Theorem 3.1 and 3.2, except the third, and the last term.

The term containing the velocity difference $(v_h - v)$ can be estimated, using $|v_h - v| + h|\nabla_\Gamma(v_h - v)| \leq ch^2$ from [DE13b, Lemma 5.6], as $ch^2 \|\nabla_\Gamma \varphi_h\|_{L^2(\Gamma(t))}$.

The nonlinear terms are rewritten as:

$$\begin{aligned} a_h^*(\widetilde{\mathcal{P}}_h u; \widetilde{\mathcal{P}}_h u, \phi_h) - a_h^*(u^{-l}; \widetilde{\mathcal{P}}_h u, \phi_h) = {} & a_h^*(\widetilde{\mathcal{P}}_h u; \widetilde{\mathcal{P}}_h u, \phi_h) - a^*(\mathcal{P}_h u; \mathcal{P}_h u, \varphi_h) \\ & + a^*(\mathcal{P}_h u; \mathcal{P}_h u, \varphi_h) - a^*(u; \mathcal{P}_h u, \varphi_h) \\ & + a^*(u; \mathcal{P}_h u, \varphi_h) - a_h^*(u^{-l}; \widetilde{\mathcal{P}}_h u, \phi_h) \end{aligned}$$

For the first and the third term Lemma 3.5 provides an upper bound $ch^2 \|\nabla_\Gamma \varphi_h\|_{L^2(\Gamma(t))}$ (similarly like before).

Finally, using Lemma 3.8 we obtain, similarly to (4), that the second term can be bounded as

$$\begin{aligned} & \big|a^*(\mathcal{P}_h u; \mathcal{P}_h u, \phi_h) - a^*(u; \mathcal{P}_h u, \phi_h)\big| \\ & = \Big| \int_{\Gamma(t)} \big(\mathcal{A}(\mathcal{P}_h u) - \mathcal{A}(u)\big) \nabla_\Gamma \mathcal{P}_h u \cdot \nabla_\Gamma \varphi_h \Big| \\ & \leq c\ell \|\mathcal{P}_h u - u\|_{L^2(\Gamma(t))} \|\nabla_\Gamma \mathcal{P}_h u\|_{L^\infty(\Gamma(t))} \|\nabla_\Gamma \varphi_h\|_{L^2(\Gamma(t))} \\ & \leq c\ell \|\mathcal{P}_h u - u\|_{L^2(\Gamma(t))} \ c\, r\ \|\nabla_\Gamma \varphi_h\|_{L^2(\Gamma(t))} \\ & \leq c\ell r\, h^2 \|\nabla_\Gamma \varphi_h\|_{L^2(\Gamma(t))}. \end{aligned}$$

□

5.2 Error estimates for the full discretizations

We compare the lifted fully discrete numerical solution $u_h^n := (U_h^n)^l$ with the exact solution $u(.,t_n)$ of the evolving surface PDE (1), where $U_h^n = \sum_{j=1}^N \alpha_j^n \chi_j(.,t)$, where the vectors α^n are generated by a Runge–Kutta or a BDF method.

Theorem 5.2 (ESFEM and R–K)**.** *Consider the evolving surface finite element method as space discretization of the quasilinear parabolic problem* (1)*, with time discretization by an s-stage implicit Runge–Kutta method satisfying Assumption 4.1. Let u be a sufficiently smooth solution of the problem, which satisfies $u(.,t) \in \mathcal{S}(t)$ $(0 \le t \le T)$, and assume that the initial value is approximated as*

$$\|u_h^0 - (\mathcal{P}_h u)(.,0)\|_{L^2(\Gamma(0))} \le C_0 h^2.$$

Then there exists $h_0 > 0$ and $\tau_0 > 0$, such that for $h \le h_0$ and $\tau \le \tau_0$, the following error estimate holds for $t_n = n\tau \le T$:

$$\|u_h^n - u(.,t_n)\|_{L^2(\Gamma(t_n))} + h\Big(\tau \sum_{j=1}^n \|\nabla_{\Gamma(t_j)}(u_h^j - u(.,t_j))\|_{L^2(\Gamma(t_j))}^2\Big)^{\frac{1}{2}} \le C\big(\tau^{q+1} + h^2\big).$$

The constant C is independent of h, τ and n, but depends on $\boldsymbol{m}$, $\mathcal{M}$, L, μ, κ and T.

Theorem 5.3 (ESFEM and BDF)**.** *Consider the evolving surface finite element method as space discretization of the quasilinear parabolic problem* (1)*, with time discretization by a k-step implicit or linearly implicit backward difference formula of order $k \le 5$. Let u be a sufficiently smooth solution of the problem, which satisfies $u(.,t) \in \mathcal{S}(t)$ $(0 \le t \le T)$, and assume that the starting values are satisfying*

$$\max_{0 \le i \le k-1} \|u_h^i - (\mathcal{P}_h u)(.,t_i)\|_{L^2(\Gamma(0))} \le C_0 h^2.$$

Then there exists $h_0 > 0$ and $\tau_0 > 0$, such that for $h \le h_0$ and $\tau \le \tau_0$, the following error estimate holds for $t_n = n\tau \le T$:

$$\|u_h^n - u(.,t_n)\|_{L^2(\Gamma(t_n))} + h\Big(\tau \sum_{j=1}^n \|\nabla_{\Gamma(t_j)}(u_h^j - u(.,t_j))\|_{L^2(\Gamma(t_j))}^2\Big)^{\frac{1}{2}} \le C\big(\tau^{k} + h^2\big).$$

The constant C is independent of h, τ and n, but depends on $\boldsymbol{m}$, $\mathcal{M}$, L, μ, κ and T.

Proof of Theorem 5.2–5.3. The global error is decomposed into two parts:

$$u_h^n - u(.,t_n) = \Big(u_h^n - (\mathcal{P}_h u)(.,t_n)\Big) + \Big((\mathcal{P}_h u)(.,t_n) - u(.,t_n)\Big),$$

and the terms are estimated by previous results.

The first one is estimated by our results for Runge–Kutta or BDF methods: Theorem 4.1 or 4.2, respectively, together with the residual bound Theorem 5.1, and by the Ritz error estimates Theorem 3.1 and 3.2.

The second term is estimated by the error estimates for the Ritz map (Theorem 3.1 and 3.2). ☐

6 Further extensions

Semilinear problems

The presented results, in particular Theorem 5.2 and 5.3, can be generalized to semilinear problems. Convergence results for BDF method were already shown for semilinear problems in [AL15]. For the analogous results for Runge–Kutta methods follow [LO95, Remark 1.1]. Problems fitting into this framework can be found in the references given in the introduction.

The inhomogeneity $f(t)$ in the evolving surface PDE (1) can be replaced by $f(t,u)$ satisfying a local Lipschitz condition (similar to (4)): for every $\delta > 0$ there exists $L = L(\delta, r)$ such that

$$\|f(t,w_1) - f(t,w_2)\|_{V(t)'} \le \delta \|w_1 - w_2\|_{V(t)} + L\|w_1 - w_2\|_{H(t)} \quad (0 \le t \le T)$$

holds for arbitrary $w_1, w_2 \in V(t)$ with $\|w_1\|_{V(t)}$, $\|w_2\|_{V(t)} \leq r$, uniformly in t. Such a condition can be satisfied by using the same $\mathcal{S}$ set as for quasilinear problems.

To be precise: In this case the bilinear form $a(.,.)$ is not depending on ξ, it is as in [DE13b]. Section 3 would reduce to recall results mainly from [DE07a, DE13b]. The stability estimates for the Runge–Kutta and BDF methods are needed to be revised in a straightforward way, cf. [LO95] and [AL15], respectively. The generalized Ritz map is the one appeared in [LM15, Man13] together with its error bounds. The regularity result of the Ritz map still needed from Section 3.7.

Deteriorating constants

In view of the cited papers, especially [LO95, Remark 1.1], Theorem 5.2 and 5.3 have an extension to the situation where the constants $\boldsymbol{m}$ and $\mathcal{M}$, in (2) and (3) are depending on $\|u\|$, and allowed to deteriorate as $\|u\|$ tends to infinity. Using energy estimates deteriorating constants can be handled for nonlinear problems. Then the constant C in Theorem 5.2 and 5.3 depends also on $\sup_{t\in[0,T]} \|u(t)\|$. For instance the incompressible Navier–Stokes equation are fitting into this framework.

7 Numerical experiments

We present a numerical experiment for an evolving surface quasilinear parabolic problem discretized by evolving surface finite elements coupled with the backward Euler method as a time integrator. The fully discrete methods were implemented in DUNE-FEM [DKNO10], while the initial triangulations were generated using DistMesh [PS04].

The evolving surface is given by

$$\Gamma(t) = \big\{x \in \mathbb{R}^3 \bigm| a(t)^{-1}x_1^2 + x_2^2 + x_3^2 - 1 = 0\big\},$$

where $a(t) = 1 + 0.25\sin(2\pi t)$, see e.g. [DE07a, DLM12, Man13]. The problem is considered over the time interval $[0, 1]$. We consider the problem with the nonlinearity $\mathcal{A}(u) = 1 - \frac{1}{2}e^{-x^2/4}$. The right-hand side f is computed as to have $u(x,t) = e^{-6t}x_1x_2$ as the true solution of the quasilinear problem

$$\begin{cases} \partial^\bullet u + u\nabla_{\Gamma(t)} \cdot v - \nabla_{\Gamma(t)} \cdot \Big(\mathcal{A}(u)\nabla_{\Gamma(t)}u\Big) = f & \text{on } \Gamma(t), \\ \qquad\qquad\qquad\qquad\qquad\qquad u(.,0) = u_0 & \text{on } \Gamma(0). \end{cases}$$

Let $(\mathcal{T}_k(t))_{k=1,2,\dots,n}$ and $(\tau_k)_{k=1,2,\dots,n}$ be a series of triangulations and timesteps, respectively, such that $2h_k \approx h_{k-1}$ and $4\tau_k = \tau_{k-1}$, with $\tau_1 = 0.1$. By e_k we denote the error corresponding to the mesh $\mathcal{T}_k(t)$ and stepsize τ_k. Then the EOCs are given as

$$EOC_k = \frac{\ln(e_k/e_{k-1})}{\ln(2)}, \qquad (k = 2, 3, \dots, n).$$

In Table 1 we report on the EOCs, for the ESFEM coupled with backward Euler method, corresponding to the norms

$$\begin{aligned} L^\infty(L^2): &\qquad \max_{1\leq n\leq N} \|u_h^n - u(.,t_n)\|_{L^2(\Gamma(t_n))}, \\ L^2(H^1): &\qquad \Big(\tau\sum_{n=1}^N \|\nabla_{\Gamma(t_n)}\big(u_h^n - u(.,t_n)\big)\|_{L^2(\Gamma(t_n))}\Big)^{1/2}. \end{aligned}$$

Figure 1 shows the errors obtained by the backward Euler method coupled with ESFEM for four different meshes and a series of time steps. The convergence in time can be seen (note the reference line), while for sufficiently small τ the spatial error is dominating, in agreement with the theoretical results.

level	dof	$L^\infty(L^2)$	EOCs	$L^2(H^1)$	EOCs
1	126	0.07121892	-	0.1404349	-

3	2070	0.00540906	1.94	0.0111377	1.86
4	8208	0.00136755	1.98	0.0033538	1.73
5	32682	0.00034289	2.00	0.0011904	1.49

Table 1: Errors and EOCs in the $L^\infty(L^2)$ and $L^2(H^1)$ norms

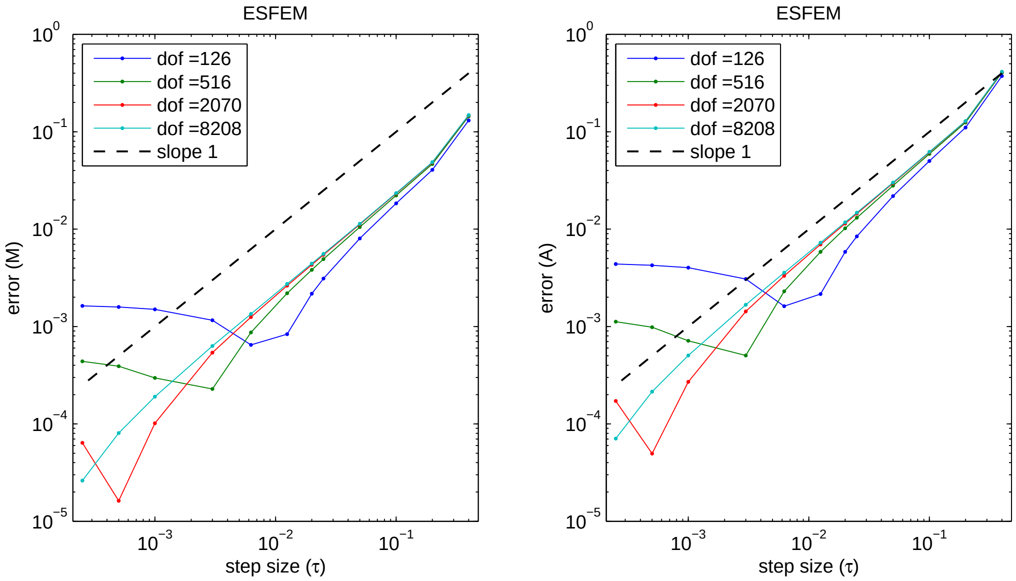

Figure 1: $\|.\|_M$-errors of the ESFEM and the backward Euler method at time $T = 1$

Figure 2 shows the errors obtained by the three step linearly implicit BDF method coupled with ESFEM for five different meshes and a series of time steps. Again the results are matching with the theoretical ones.

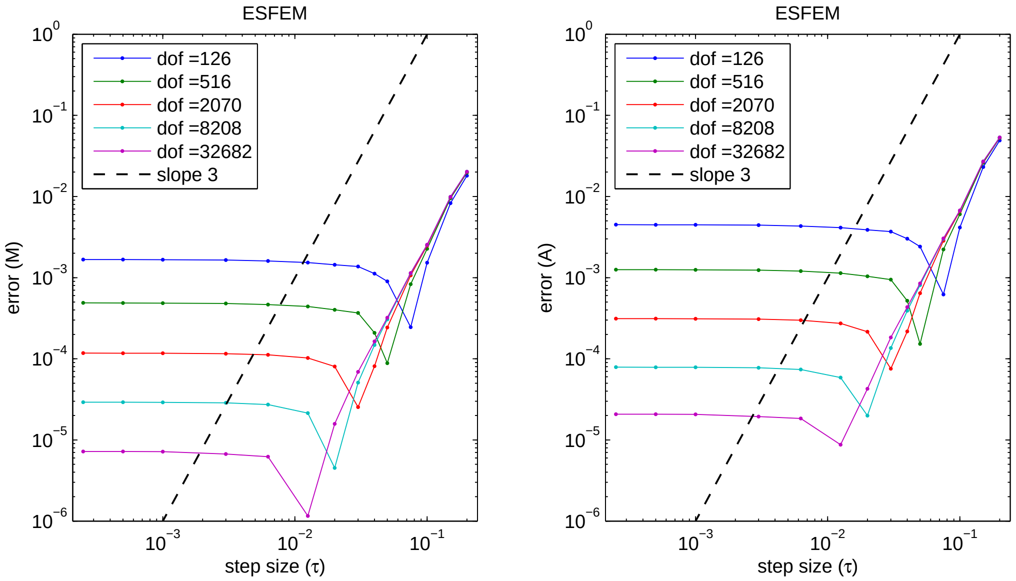

Figure 2: $\|.\|_{\mathbf{A}}$-errors of the ESFEM and the 3 step linearly implicit BDF method at time $T = 1$

We note that, for this example, no significant difference appeared between the fully implicit and linearly implicit BDF methods.

Acknowledgement

The authors would like to thank Prof. Christian Lubich for the invaluable discussions on the topic and for his encouragement and help during the preparation of this paper. We would also like to thank Prof. Frank Loose and Christopher Nerz for our discussions on the topic. The research stay of B.K. at the University of Tübingen has been funded by the Deutscher Akademischer Austausch Dienst (DAAD).

Appendix A: A priori estimates

The result presented here gives regularity result, with a t independent constant, for the elliptic problems appeared in the proofs of the errors in the Ritz map.

Theorem A.1 (Elliptic regularity for evolving surfaces). *Let $\Gamma(t)$ be an evolving surface, fix a $t \in [0,T]$ and a function $\xi\colon \Gamma(t) \to \mathbb{R}$.*

(i) Let $f \in H^{-1}\big(\Gamma(t)\big)$ and

$$L(u) := -\nabla_\Gamma \cdot \big(\mathcal{A}(\xi)\nabla_\Gamma u\big) + u. \tag{19}$$

Then there exists a weak solution $u \in H^1\big(\Gamma(t)\big)$ of the problem

$$L(u) = f \tag{20}$$

with the estimate

$$\|u\|_{H^1(\Gamma(t))} \leq c\|f\|_{H^{-1}(\Gamma(t))}, \tag{21}$$

where the constant above is independent of t.

(ii) Let $L(u)$ be (19), let $f \in L^2\big(\Gamma(t)\big)$ and let $u \in H^1\big(\Gamma(t)\big)$ be a weak solution of (20). Then u is a strong solution of (20), i.e. u solves (20) almost everywhere and there exists a constant $c > 0$ independent of t and u such that

$$\|u\|_{H^2(\Gamma(t))} \leq c\big(\|u\|_{L^2(\Gamma(t))} + \|f\|_{L^2(\Gamma(t))}\big).$$

Proof. For (i): The Lax–Milgram lemma shows the existence of the weak solution u. Because the coercivity and boundedness constants (2) and (3) are independent of t, the constant in (21) also not depends on t. For (ii): Basically we consider pullback of the operator L to $\Gamma(0)$, rewrite it in a local chart and then apply the corresponding results of [GT83].

By assumption there exists a diffeomorphic parametrization of our evolving surface $\Gamma(t)$, i.e. we have a smooth map

$$\Phi\colon \Gamma(0) \times [0,T] \to \mathbb{R}^{m+1}$$

such that

$$\Phi_t\colon \Gamma(0) \to \mathbb{R}^{m+1}, \quad \Phi_t(x) := \Phi(x,t)$$

is an injective immersion which is a homeomorphism onto its image with $\Phi_t\big(\Gamma(0)\big) = \Gamma(t)$. Because $\Gamma(0)$ is compact, there exists a finite atlas

$$\Big(\varphi_n(0)\colon U_n(0) \subset \Gamma(0) \to \mathbb{R}^m\Big)_{n=1}^k$$

such that $\varphi_n\big(U_n(0)\big) \subset \mathbb{R}^m$ is bounded and a finite family of compact sets $\big(V_n(0)\big)_{n=1}^k$ with $V_n(0) \subset U_n(0)$, and $\bigcup_{n=1}^k V_n(0) = \Gamma(0)$. Using the properties of the diffeomorphic parametrization the new collections,

$$V_n(t) := \Phi_t\big(V_n(0)\big), \quad U_n(t) := \Phi_t\big(U_n(0)\big), \quad \varphi_n(t) := \varphi_n(0) \circ \Phi_t^{-1},$$

still have the same properties. Now consider the following standard formulae of Riemannian geometry [Eck04]:

$$\nabla_\Gamma h(x,t) = \sum_{i,j=1}^m g_n^{ij}(x,t) \frac{\partial(h \circ \varphi_n(t)^{-1})}{\partial x^i} \frac{\partial\big(\varphi_n(t)^{-1}\big)}{\partial x^j},$$

where

$$g_{ij,n}(x,t) := \frac{\partial\big(\varphi_n(t)^{-1}\big)}{\partial x^i} \cdot \frac{\partial\big(\varphi_n(t)^{-1}\big)}{\partial x^j}\Bigg|_x$$

is the first fundamental form and $g_n^{ij}(x,t)$ are entries of the inverse matrix of $g_n := (g_{ij,n})$, and

$$\nabla_\Gamma \cdot X = \sum_{i,j=1}^m \frac{1}{\sqrt{g_n}} \frac{\partial}{\partial x^i}\big(\sqrt{g_n} g_n^{ij} X_j\big)$$

where X is a smooth tangent vector field with $X_j = X \cdot \frac{\partial(\varphi(t)^{-1})}{\partial x^j}$ and $\sqrt{g_n} := \sqrt{\det(g_n)}$. It is straightforward to calculate that

$$\Big(-\nabla_\Gamma \cdot \mathcal{A}\nabla_\Gamma u + u\Big) \circ \varphi_n(t)^{-1}(x) = \sum_{i,j=1}^m a_{ij,n}(x,t) \frac{\partial^2\big(u \circ \varphi_n(t)^{-1}\big)}{\partial x^i \partial x^j} + \sum_{i=1}^m b_{i,n}(x,t) \frac{\partial\big(u \circ \varphi_n(t)^{-1}\big)}{\partial x^i} + c_n(x,t)\, u \circ \varphi_n(t)^{-1}$$

for some appropriate functions $a_{ij,n} \in W^{1,\infty}\big(U_n(t)\big)$, $b_{i,n}, c_n \in L^\infty\big(U_n(t)\big)$ where $a_{ij,n}$ represents a uniform elliptic matrix. Observe that the assumptions (2), (3) and (4) implies that the function above can be bounded independently of t. Now [GT83, Theorem 8.8] states that, if $u \circ \varphi_n(t)^{-1}$ is the H^1-weak solution of (20), then it must be a strong solution as well.

For the estimate in (ii) observe that [GT83, Theorem 9.11] gives us for $V_n(t)$ in particular the estimate

$$\|u \circ \varphi_n(t)^{-1}\|_{H^2(V_n'(t))} \leq c(\|u \circ \varphi_n(t)^{-1}\|_{L^2(U_n'(t))} + \|f \circ \varphi_n(t)^{-1}\|_{L^2(U_n'(t))}), \tag{22}$$

where $V_n' := \varphi_n(t)\big(V_n(t)\big)$ and $U_n' := \varphi_n(t)\big(U_n(t)\big)$ are obviously independent of t. Thus the constant above is independent of t. Then Theorem 3.41 in [AF03] shows that

$$\|u\|_{H^2(V_n(t))} \leq c(t)\|u \circ \varphi_n(t)^{-1}\|_{H^2(V_n'(t))} \leq c\|u \circ \varphi_n(t)^{-1}\|_{H^2(V_n'(t))},$$

where the constant in the middle depends continuously on t, hence the last constant is independent of t. A similar estimate holds for the right-hand side of (22). An easy calculation finishes the proof for (ii). □
